ABSTRACT
Visceral adipose tissue-derived serine protease inhibitor (vaspin) is an adipokine associated with insulin resistance (IR), obesity, and inflammation. Serum vaspin role and significant alteration in its levels in type 2 diabetes mellitus (T2DM) and atherosclerotic disease have been severally reported. Nevertheless, these immense changes and this role have been studied, and different results were observed across several atherosclerosis and glucose tolerance disorders-associated studies due to differences in design, sample size and baseline parameters, and population race. Hence, we performed a systematic review to establish and summarize the latest results of serum vaspin level alteration and its role in atherosclerosis and glucose tolerance disorders. The studies from databases such as PubMed, ScienceDirect, Scopus, and Google Scholar were employed. The keywords included vaspin, atherosclerosis, coronary heart disease, ischemic heart disease, shock, insulin, diabetes, glucose intolerance, metabolic syndrome, and obesity. Boolean Logic “AND” was used to combine each keyword and specify the results. Twenty-three articles were selected based on the suitability of their title/abstract and the inclusion criteria for this review topic. Two review authors independently evaluated the risk of bias based on the Cochrane risk of bias tool. Furthermore, we used RevMan 5.3 to present and synthesize the results. Critical appraisal of each obtained article showed that high vaspin levels were associated with a lower risk of atherosclerosis. Meanwhile, 10 articles about vaspin and glucose tolerance disorders showed that high vaspin levels were associated with a higher risk of developing T2DM. Meta-analysis showed atherosclerotic diseases and glucose tolerance disorders versus normal healthy (MD −0.43; 95% CI: −1.35 to 0.50 and MD −0.07; 95% CI: −0.38 to 0.25, respectively), which indicated higher vaspin levels in the disease group were favored. High serum vaspin levels in arterial plaque diseases were considered a protective mechanism to prevent further endothelial inflammation, injury, and atherosclerosis. This similar observation was found in obesity or T2DM patients as a compensatory mechanism for IR conditions.

INTRODUCTION
Based on the traditional theory, adipose tissue is inert, and it regulates body temperature, stores fat, supplies energy, absorbs shock, and functions as an insulator. However, recent studies described it as an endocrine organ with multiple functions and active metabolism (Coelho et al., 2013). The factors influenced by adipose tissue secretion and metabolism are called adipokines which perform a substantial role in obesity, metabolic syndrome, atherosclerosis, and blood glucose regulation (Kim and Choi, 2020). Furthermore, they serve as growth factors, cytokines, acute phase reactants, other inflammatory mediators, adipose tissue-secreting hormones such as leptin and adiponectin, and biochemical messengers (Kang et al., 2016).
Vaspin, also known as SERPINA12 according to serpin nomenclature, is a unique insulin-sensitizing adipocytokine discovered by Hida et al. (2005) and was associated with the development of inflammation and metabolic syndrome. It was first discovered in the visceral adipose tissue (VAT) of Otsuka Long-Evans Tokushima fatty (OLETF) rat, an animal model with type 2 diabetes mellitus (T2DM) and truncal obesity.

Previous investigations of vaspin role in metabolic and vascular diseases produced conflicting and various results because the levels are always inconstant in both conditions. A study associated the increase of serum vaspin concentration in mice with central obesity and insulin resistance (IR) (Liu et al., 2018). However, vaspin has been presumed to be an insulin sensitizer with anti-inflammatory effects and might act as a compensatory process in response to IR (Wada, 2008). Furthermore, a study showed no significant vaspin role concerning insulin sensitivity in non-diabetic healthy humans (Von Loeffelholz et al., 2010).

A further study reported that VAT-derived adipokines such as vaspin have a local and endocrine function in developing early and late atherosclerosis in obesity by affecting vascular smooth muscle cells (VSMCs) of the endothelium (de Leal and Mafra, 2013). Meanwhile, another study stated that vaspin serum level is not related to carotid stenosis plaque severity, but its low level is associated with the risk of ischemic events in carotid stenosis patients (Aust et al., 2009).

Therefore, we conducted a systematic review and meta-analysis to determine the serum vaspin level alteration role in atherosclerosis and glucose tolerance disorders. We also conducted a critical appraisal of all selected articles to establish the serum vaspin role in atherosclerosis and glucose tolerance disorders. A common understanding and conclusion were eventually developed from the different assessed results.

Moreover, a brief additional review of the serum vaspin basic biochemical role and its genetic expression and polymorphism factor was also conducted. However, we did not consider and further analyze the relationship between genetic expression-polymorphism factor and serum vaspin levels in this study.

**METHODS**

A literature search was conducted using scientific databases such as PubMed, ScienceDirect, Scopus, and Google Scholar from September 2021 to January 2022. We performed this search based on the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) flowchart for the selection of studies (Page et al., 2021). Combinations of keywords associated with “vaspin” AND “glucose intolerance” including diabetes, hyperglycemia, and insulin plus either “atherosclerosis” involving coronary heart disease, ischemic heart disease, and stroke, “metabolic syndrome,” OR “obesity” were employed. The inclusion criteria included English language studies published between 2005 and 2022 with clinical or laboratory experimental and non-experimental designs (cohort, case-control, and cross-sectional), as well as discussing vaspin serologically rather than in terms of genetic expression. Several *in vitro* and *in vivo* studies were also considered to provide insight into the potential mechanism of vaspin in atherosclerosis and glucose intolerance. Moreover, the citation-reference lists from the selected studies were also investigated to recognize related results.

The eligibility of the titles and abstracts was independently reviewed by two authors (RD and FM) based on the Cochrane Handbook for Systematic Reviews. Initially, 146 articles were obtained, including 92 derived from the keywords of “vaspin” AND “glucose intolerance” OR “atherosclerosis” and 54 from “vaspin” AND “metabolic syndrome” combination OR “obesity.” A total of 95 articles were excluded after manual investigation for unavailable full text and duplications. The articles were extracted using a data extraction template (Microsoft Office Excel 2016). We used the Cochrane risk of bias tool to assess the risk of bias in the included studies. This tool evaluates six potential issues: sequence generation, allocation concealment, incomplete data, blinding, selective outcome reporting, and other bias-related issues. Then, we screened again the eligibility of each article’s title and abstract, and eventually, 23 eligible articles were selected to be reviewed (Fig. 1). These articles were then exported and compiled by the Mendeley Citation Manager.

The selected articles used immunoassays product of Vaspin ELISA (Mediagnost Vaspin ELISA E106) by BioVendor R&D® (Asheville, NC). This Vaspin ELISA product uses a serum sample to quantify the vaspin concentration. It has a sensitivity of 4 pg/ml. Its reagents and material equipment provided included a microtiter-plate, recombinant vaspin, dilution buffer, control sera, antibody conjugate, enzyme conjugate, washing buffer, substrate, stopping solution, and sealing tape for covering the microtiter plate. We also ensured that the selected articles used the standardized statistical analysis software of Statistical Package for the Social Sciences, at least the 22nd version.

The 23 articles were reviewed and analyzed by standard common questions for the critical appraisal (Al-Jundi and Sakka, 2017). The critical appraisal questions included the research objective or question, study design, selection issues, outcome factors, study factors, important potential confounders, statistical method used, statistical results, main conclusions about the research objective or question, and ethical issues considered. Data synthesis and statistical analysis were performed using RevMan version 5.4 for Windows. The authors conducted a subgroup analysis and meta-regression of heterogeneous papers and the relationship between serum vaspin levels and atherosclerotic-glucose tolerance diseases based on their respective study designs.

The study location was also considered due to population race effects on vaspin gene expression and polymorphism. However, this review did not analyze vaspin gene expression and polymorphism in detail but compared the data analysis components of every article. Finally, a common agreement and conclusion were reached concerning serum vaspin role in atherosclerosis and glucose tolerance disorders.

**RESULTS AND DISCUSSION**

We reviewed 23 studies investigating serum vaspin role in atherosclerosis and glucose tolerance disorders (Tables 1 and 2). In those tables, the authors also gave specific significant remarks to explain why the selected study was being listed. We also presented the risk of bias in the included studies in Figures 2 and 3. The forest plots of the meta-analysis showed atherosclerotic diseases
versus normal healthy (MD −0.43; 95% CI: −1.35 to 0.50) (Fig. 4) and glucose tolerance disorders versus normal healthy (MD −0.07; 95% CI: −0.3 to 80.25) (Fig. 5). Those results indicated that higher vaspin levels in the disease group were preferred.

Mode of action and mechanism of vaspin

Vaspin is an adipokine with targets in kallikrein 7 (KLK) and KLK 14, which are involved in skin desquamation. This VAT-derived serine protease inhibitor has been identified to significantly increase in 30 weeks of OLETF (Hida et al., 2005). Once the circulatory or adipocyte vaspin concentration hits the peak in IR and obesity, the expression of this compound increases significantly. Furthermore, a study showed that KLK 7 co-expressed in rat islets suggests promising relevance of the vaspin-KLK7 mode of inhibition in early insulin secretion (Heiker et al., 2013) (Fig. 6). Meanwhile, the insulin sensitizers of pioglitazone normalize both vaspin serum levels and expression (Wada, 2008).

Vaspin is believed to act as an insulin sensitizer with a compensatory role in white adipose tissue because the favorable effect is involved in the gene expression of IR pathogenesis, including tumor necrosis factor-α (TNF-α), leptin, resistin, glucose transporter-4, and adiponectin (Li et al., 2008). It is considered that vaspin synthesis antagonizes the effect of uninvestigated proteases, which interrupt insulin action (Dwipayana et al., 2019). It could be compared to other proteins, such as neutrophil elastase and α1-antitrypsin (D’Souza et al., 2021; Motoyama et al., 2020).

Vaspin and atherosclerosis

In obesity-associated inflammation and cardiovascular diseases, several studies showed the establishment of vaspin anti-atherogenic and anti-inflammatory roles on smooth muscle and vascular endothelial cells. Evidence demonstrates that it protects endothelial cells from apoptosis and inflammation (Fig. 6). Vaspin inhibits TNF-α-induced expression of adhesion molecules in VSMCs and later reduces lymphocyte adhesion by decreasing reactive oxygen species (ROS), protein kinase C, and nuclear factor-κB (NF-κB) activation. Additionally, the blockade of ROS production attenuates and reduces cytoskeletal reorganization, platelet-derived growth factor (PDGF), and intercellular adhesion molecule 1 (ICAM1) expression (Li et al., 2013).

According to the critical appraisal in Table 1, seven studies, three cross-sectional, two cohorts, one case-control, and one interventional in vivo, suggested that vaspin has a protective and beneficial effect on atherosclerosis progression (Aust et al., 2009; Jung et al., 2011; Kastl et al., 2020; Li et al., 2012; Zhang et al., 2013, 2016, 2020). However, those three cross-sectional studies failed to indicate the cause-effect relationship of vaspin with atherosclerosis. A result showed confounding factors, including 52.5% of patients using angiotensin-converting enzyme inhibitors.
Table 1. Critical appraisal from the review of the association between vaspin serum level and atherosclerosis.

</table>

Serum vaspin levels in men vs. women:
- Median (IQR) 0.60 (0.40–0.99) vs. 0.40 (0.26–0.66) ng/ml, p = 0.002.
- No significant difference in women (0.51 (0.30–0.97) vs. 0.53 (0.27–0.99) ng/ml, p = 0.821).

Correlation of vaspin with metabolic parameters:

- Men:
  - r = 0.278, p < 0.001 (fat%)
  - r = 0.221, p = 0.003 (BMI)
  - r = 0.196, p = 0.005 (waist circumference)
  - r = 0.159, p = 0.031 (TG)
  - Correlation with metabolic parameters was stronger in men.

- Women:
  - Stronger correlation observed with other metabolic parameters.

Men and women:
- Significant differences in plasma vaspin levels by gender.
- Correlation with metabolic parameters observed, though stronger in men versus women.
inhibitors or angiotensin receptor blockers and 66.3% receiving β-blockers (Zhang et al., 2016).

Meanwhile, four studies, three cross-sectional and one cohort, demonstrated that serum vaspin elevation causes atherosclerosis (Choi et al., 2011; Cura et al., 2014; El-Lebedy et al., 2018; Esaki et al., 2014). Those three cross-sectional types stated no conclusive relationship between vaspin and atherosclerosis. One cross-sectional study had limitations due to small sample size with a relatively homogenous normal profile of body mass index (BMI), carotid intima-media thickness, and IR homeostatic model assessment (Esaki et al., 2014).

### Vaspin and glucose tolerance disorders

Several studies showed a positive correlation of serum vaspin levels with waist fat mass, circumference, and BMI, while the higher levels in obese and T2DM patients are possibly the consequence reaction of IR (Jian et al., 2014). Another study explained this pathophysiology that the expression of insulin receptor substrate-2 messenger RNA (mRNA) was increased by administering 80–320 ng/ml vaspin. The VAT-derived serine protease inhibitor stimulated insulin secretion by the insulinoma cell line mediated through kinase Akt activation and the mTOR/p70S6K signaling pathway (Liu et al., 2017). It was also reported to increase β-cell activity by impeding the KLK 7 and KLK 14 inhibition function (Heiker et al., 2013) (Fig. 6).

Pancreatic cell inflammation was inhibited by vaspin through NF-κB downregulation (Liu et al., 2017). It is an important fact that T2DM is associated with a chronic inflammatory process mediated by cytokines. Subsequently, high inflammatory cytokine in the pancreatic islets of T2DM patients causes pancreatic β-cell failure and activity impairment (Donath et al., 2009; Nordmann et al., 2017). Hence, high serum vaspin levels improve the β-cell function in patients with glucose tolerance disorders (Jian et al., 2014; Liu et al., 2017).

Based on the critical appraisal in Table 2, this current review indicated that 10 studies, 8 cross-sectional, 1 case-control, and 1 interventional human, demonstrated higher vaspin levels in glucose tolerance disorder patients (Dai et al., 2016; El-Mesallamy et al., 2011; Lal et al., 2018; Liu et al., 2020; Moradi et al., 2016; Yang et al., 2015, 2017a, 2017b; Ye et al., 2009; Youn et al., 2008). As stated in the previous review, all the cross-sectional types did not determine the cause–effect relationship between vaspin and T2DM. Furthermore, one interventional study showed that vaspin plays a role in compensating the insulin physiological and sensitivity function in IR conditions (Youn et al., 2008). The compound is believed to have no significant role in healthy normal subjects and physically active persons (Youn et al., 2008). A case-control study that evaluates the genotype and allele frequency in gestational diabetes mellitus (GDM) showed very little inconsistency in the relationship between vaspin levels and GDM compared with other existing reports. Conversely, the vaspin gene with a predominance of the AA genotype has been said to increase the risk of developing metabolic syndrome more than TT or TA (Lal et al., 2018).

A positive association of serum vaspin level with IR risk has been reported in all adolescents at the pubertal stage and their counterparts with a high percentage of body fat (%BF). Higher

<td><strong>Brazil (Pala et al., 2019)</strong></td>
<td>Determine the association between serum vaspin levels and IR and investigate whether this association is affected by body composition and pubertal stage in adolescents during 300 minutes of physical activity per week for 6 months.</td>
<td>Cross-sectional and case-control; population study (484).</td>
<td>This study used adolescents aged 10–14 years. It is well known that IR becomes more common at a young age.</td>
<td>Simple random sampling; reliability (reproducibility) and validity were reported. Controls were appropriate; records of cases and controls were reviewed blindly; prevalence bias, admission rate bias, and recall bias were controlled. Droopout bias was not controlled.</td>
<td>All relevant outcomes were assessed. Measurement error was not detected.</td>
<td>Relevant study factors were included in the study, and they were measured using appropriate tools.</td>
<td>Vaspin affects IR directly because insulin metabolism adjustment is possibly affected by regular physical activity; 180 adolescents did not complete the physical activity protocol; confounding variables included sex, age, BMI, %BF, pubertal stage, and physical activity.</td>
<td>The Mann–Whitney U and Pearson's $r^2$-tests were used to compare continuous and categorical risk variables between %BF groups.</td>
<td>In all adolescents' pubertal stage, there is an association between vaspin and age, insulin, and HOMA-IR ($r$ = 0.10, $p$ = 0.03; $r$ = 0.8, $p$ &lt; 0.001; and $r$ = 0.16, $p$ = 0.002, respectively). In the high %BF group, there is an association between vaspin and BMI, triacylglycerol, insulin, and HOMA-IR ($r$ = 0.17, $p$ = 0.018; $r$ = 0.18, $p$ = 0.014; $r$ = 0.25, $p$ = 0.001; and $r$ = 0.23, $p$ = 0.003, respectively). Adolescents in the second ($\leq 0.25$–0.46, $\geq 0.36$–0.65 µg/ml), third ($\leq 0.47$–0.86, $\geq 0.66$–1.49 µg/ml), OR = 0.48, [95% CI = 0.26–0.87], $p$ = 0.015) serum vaspin quartiles had a lower risk of developing IR than in the fourth quartile ($\leq 0.87$, $\geq 1.50$ µg/ml).</td>
<td>Vaspin was associated positively with risk factors related to insulin metabolism in adolescents with high %BF; vaspin was related to a reduced risk of IR independently of BMI and pubertal stage; that association was influenced by body fat and physical activity in adolescents.</td>
<td>The Ethics Committee of the Federal University of Ouro Preto, Minas Gerais, Brazil, gave approval (No. 0017.238.000-05) for this study.</td>
</tr>
<tr>
<td><strong>Pakistan (Lal et al., 2018)</strong></td>
<td>Investigate and associate serum vaspin levels and genotype and allele frequency in GDM.</td>
<td>Case-control; single-center (112).</td>
<td>The glucose tolerance disorders were presented by GDM pregnant women instead of T2DM patients.</td>
<td>Controls were appropriate; records of cases and controls were reviewed blindly; prevalence bias, admission rate bias, lead time bias, and recall bias were controlled.</td>
<td>All relevant outcomes were assessed. Measurement error was not detected.</td>
<td>Relevant study factors were included in the study, and they were measured using appropriate tools.</td>
<td>Statistical descriptive analysis of continuous variables was expressed as mean ± SD. $t$-test was performed to compare groups.</td>
<td>Serum vaspin levels were lower in the healthy group than in GDM ($p$ = 0.041). No significant difference in genotype and allele frequencies regarding serum vaspin levels ($p$ = 0.330, $p$ = 0.327, respectively).</td>
<td>Higher plasma vaspin concentrations were seen in GDM females.</td>
<td>Approval was obtained from the Aga Khan University Ethics Committee, and participants signed written consent.</td>
<td></td>

<tr>
<td><strong>China (Yang et al., 2015)</strong></td>
<td>Determine the changes in serum vaspin concentration in early diagnosed T2DM patients to investigate the relationship between serum vaspin level, BMI, and gender.</td>
<td>Cross-sectional; single-center (66).</td>
<td>This study used vaspin ELISA measurement assays with the lowest measurable concentration of 0.05 mg/l. Moreover, it also determines the vaspin levels in regard to gender.</td>
<td>Simple random sampling; reliability (reproducibility) and validity were not reported.</td>
<td>All relevant outcomes were assessed. Measurement error was not detected.</td>
<td>Relevant study factors were included in the study, and they were measured using appropriate tools.</td>
<td>Potential confounders were not found.</td>
<td>Data are reported as means ± SD. The $t$-test, chi-square test, linear correlation analysis, and stepwise multiple regression were performed.</td>
<td>Average serum vaspin levels were significantly higher ($p &lt; 0.001$) in obese patients (1.13 ± 0.25 mg/l) than in nonobese patients in both the DM group (0.65 ± 0.13 mg/l) and control group (0.38 ± 0.18 mg/l). There is significant difference in vaspin level in the T2DM group ($\leq 0.76$ ± 0.22, $\geq 0.92$ ± 0.35 mg/l, $p &lt; 0.001$) and in the control group ($\leq 0.48$ ± 0.14, $\geq 1.05$ ± 0.21 mg/l, $p &lt; 0.001$).</td>
<td>Serum vaspin concentrations were significantly increased in obese people and were independently associated with WHR and gender.</td>
<td>The Ethics Committee of the Affiliated Hospital of Jiangsu University approved this study protocol.</td>

<td>Iran (Moradi et al., 2016)</td>
<td>Evaluate the effect of serum vaspin levels on RMR in obese people.</td>
<td>Cross-sectional; population study (222).</td>
<td>This study evaluated the vaspin level in regard to gender and RMR in obese people. Furthermore, the RMR was measured by means of calorimetry. It was measured by indirect calorimetry after 10–12 hours of overnight fasting.</td>
<td>Simple random sampling; reliability (reproducibility) and validity were reported.</td>
<td>All relevant outcomes were assessed. Measurement error was not detected.</td>
<td>Relevant study factors were included in the study and they were measured using appropriate tools.</td>
<td>High and low levels of the vaspin group were assessed by the independent t-test. The chi-square test was performed for comparison of the frequencies of variables between different groups in sex analysis.</td>
<td>There was no significant difference of RMR between the low (&lt;0.70 ng/ml) and high (&gt;0.70 ng/ml) vaspin level groups (mean ± SD, 1,653.50 ± 352.70 vs. 1,658.02 ± 352.19, 95% CI: -8.73 to 97.73, p = 0.920). Between low and high vaspin level groups, there was significant difference for sex (p = 0.03), %BF (p = 0.008), RMR per BW (p &lt; 0.001), and RMR per FFM (p = 0.007).</td>
<td>In obese individuals, serum vaspin level is higher in women than in men; serum vaspin had a mediator effect between visceral fat and fat mass associations with RMR in an obese person.</td>
<td>The Local Ethics Committee of Tehran University of Medical Sciences approved the study protocol (Ethic No.: 91-02-27-18041-69439).</td>

</tbody>
</table>
serum vaspin level (♀: ≥0.87, ♂: ≥1.50 µg/ml) was linked with a reduced IR risk independently of BMI, %BF, and pubertal stage (Pala et al., 2019). Those results did not conclude whether serum vaspin level affects IR directly because the insulin metabolism adjustment is possibly affected by regular physical activity. Insulin has a propensity to be the factor affecting serum vaspin levels. Nevertheless, the aforementioned study proves that the association between higher serum vaspin levels and lower risk for IR tends to be mediated by physical activity in adolescents. However, there were actual result biases, including 180 adolescents who did not complete the physical activity protocol (Pala et al., 2019). One interventional human study also produced unusual results, which suggested that the longer intervention duration further elucidates the nonsignificant difference between the intervention and control saline groups (Von Loeffelholz et al., 2010).

Vaspin and gender difference

The majority of the studies showed that serum vaspin concentrations were significantly higher in females than in males. Vaspin levels elevated with pubertal stage and age in females, but they were constant in males (Körner et al., 2011). The mechanism between serum vaspin levels and gender differences remains unsettled. Circulating estrogen concentration has been said to elevate serum leptin levels. This tends to also elucidate the elevated vaspin levels in females (Yang et al., 2015). A study reported GRP78 mRNA expression and vaspin levels in porcine oocyte and ovarian follicles (Kurowska et al., 2019). Those vaspin genes and serum depend on the ovarian follicle cycle while serum vaspin increases from the early to the late luteal phase (Kurowska et al., 2020).

A cross-sectional case-control study showed significantly high vaspin levels in females with polycystic ovary syndrome (PCOS). Those individuals had stimulatated vaspin mRNA expression and its protein product in omental adipose tissue (Dogan et al., 2020). Consequently, PCOS is highly associated with peripheral IR, hyperinsulinemia, and obesity (Kazemi Jaliseh et al., 2017).

Serum vaspin level and its genetic expression

Serum vaspin is regulated and encoded by the SERPINA12 gene consisting of 1,245 nucleotides on the 14q32.1 human chromosome (Hida et al., 2005). This review did not consider vaspin genetic expression aspects; hence, the vaspin expression and serum concentration are indirectly influenced by the gene and single nucleotide polymorphisms (SNPs) role (Fig. 6). Moreover, each type of vaspin gene SNP is strongly influenced by population race.

In the Japanese population, the SNPs restriction site (rs) 77060950 indicated high serum levels by modulating vaspin protein transcription (Teshigawara et al., 2012). Another study on the serum vaspin concentration and T2DM in the Iranian population showed that rs2236242 allele A is protective for T2DM and it indirectly causes a low vaspin level compared to T. According to Hosseini et al. (2021), rs2236242 SNPs have no association with IR. Therefore, the population race and its most suitable SNP type need to be considered in every vaspin serological study. Therefore, the population race and its most suitable SNP type need to be considered in every vaspin serological study.

Figure 3. Risk of bias graph by the authors’ judgments for each reviewed study.

Figure 4. Forest plot of serum vaspin levels (ng/ml) comparison between atherosclerotic diseases and normal healthy. CI, confidence interval and SD, standard deviation.
**Figure 5.** Forest plot of serum vaspin levels (ng/ml) comparison between glucose tolerance disorders and normal healthy. CI, confidence interval and SD, standard deviation.

**Figure 6.** Anti-inflammatory, anti-atherosclerotic, and IR compensatory molecular pathways that are affected by serum vaspin. Vaspin showed a beneficial role in endothelial cells; meanwhile, vaspin increases insulin levels as a compensatory mechanism due to IR. eNOS, endothelial nitric oxide synthase; FPG, fasting plasma glucose; ICAM1, intracellular adhesion molecule 1; IL, interleukin; IRS-1, insulin receptor substrate 1; KLK, kallikrein; NF-kB, nuclear factor-κB; NO, nitric oxide; PDGF, platelet-derived growth factor; pNOS, phosphorylated endothelial nitric oxide synthase; ROS, reactive oxygen species; SNPs, single nucleotide polymorphisms; TNF-α, tumor necrosis factor-alpha; and WAT, white adipose tissue.
CONCLUSION

High serum vaspin levels represent insulin compensatory adipokines during IR conditions in T2DM or obesity. Consequently, the levels of this compound significantly increase in patients with glucose intolerance. In vascular studies, a high serum vaspin level demonstrates a favorable role and beneficial effect in preventing atherosclerosis in either VSMCs or endothelial cells. The main limitation of this review was a failure to consider the effect of population SNP types on serum vaspin levels. Hence, a further review needs to include a detailed discussion of vaspin gene expression, population race, and specific SNP types.
